Project 1 (30% of Module)

Client – Server Application

Instructions:

1. Create a Support Ticketing system application **in PHP.**
   The purpose of this assignment is to introduce the concept of working with a MySQL database along with Client-side (JavaScript) and Server-side (PHP) processing.
   It will also introduce the concepts of website management and storyboarding.

2. The solution is to be presented in a **report**. The report is to
   - define the purpose of your Support Ticketing System and its operation
   - contain a storyboard depicting the overall plan of the Ticketing System.
   - For each function, include a short description, and a screenshot of the web page(s) in that area, along with the Client side (minimal) and Server-side code of each page. (No need to print out HTML, or CSS code).
   - The report is also to contain a screenshot of the tables of the database used.

   Include any assumptions which you have used.

3. The work you do must be available for inspection in addition to the report.

4. Due Date: **October 18th 2024**

Specification of functionality:

This is an application used to implement a Helpdesk Ticketing System.
It has two areas: The Support area and the User area.

- In the **Support area**, a support agent may
  - Search Open Tickets
  - Resolve an open ticket
  - Elevate an open ticket
- In the **User area**, a user may
  - Register

- A registered user may
    - Login, Logout
    - Open a ticket
    - Check ticket status (My Tickets) (open, resolved, closed)
    - Close a ticket

Ticket Status:

A ticket can be in one of three statuses: **Open, Resolved** or **Closed**.

When a ticket requires any action from an agent, it is marked as **Open**. That means every new ticket would be marked as Open by default.

When an agent provides a solution, it is marked as **Resolved**.

Once an agent has provided a solution to their ticket, the user can **Close** the ticket.

If an agent can't resolve a ticket, it may be required to be elevated to an agent with a higher support level and the status of the ticket will remain Open.

Details to be stored on

- A Support Agent could include; Agent ID, username for login, password, Full name, support level
- A User could include; a User ID, username for login, password, Full name
- A Ticket could include; ticket ID, subject, ticket description, status, date submitted, resolution details etc.

Approaching this problem:

1. Understand the requirements
2. Draw up the storyboard design
3. Build some prototype screens and then commence!
4. Identify good UX practices and make the application user centered.

Report Layout:

Title Page, Table of Contents, Page numbers

Suggested Section headings

Section 1: Introduction

Section 2: Ticketing System- what is and how it operates

Section 3: Storyboard of application

Section 4: Tables Used

Section 5: For each function: short description, a screenshot of the web page(s) in that area, along with the Client side and Server-side code of each page.

Section 6: UX Decisions
